INTRODUCTION TO AI

ADVERSARIAL GAMES

BEHAVIOR FROM COMPUTATION

TYPES OF GAMES

- ▶ Many different kinds of games
- ▶ Axes:
 - ▶ Deterministic vs. stochastic
 - ▶ One, two, or more players
 - ▶ Zero sum
 - ▶ Perfect information (can you see the state)
- ▶ Algorithms need to calculate a strategy (**policy**) which recommends a move from each state

Assignment Project Exam Help
<https://powcoder.com>
Add WeChat powcoder

DETERMINISTIC GAMES

- ▶ Problem formulation:

- ▶ States: S (start at s_0)

- ▶ Players: $P=\{1\dots N\}$ (usually take turns)

Assignment Project Exam Help

<https://powcoder.com>

- ▶ Actions: A (may depend on player / state)

Add WeChat powcoder

- ▶ Transition Function: $S \times A \rightarrow S$

- ▶ Terminal Test: $S \rightarrow \{t, f\}$

- ▶ Terminal Utilities: $S \times P \rightarrow R$

- ▶ Solution for a player is a **policy**: $S \rightarrow A$

ZERO-SUM GAMES

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

▶ Zero-Sum Games

- ▶ Agents have opposite *utilities* (values on outcomes)
- ▶ Can then think of outcome as a single value that one maximizes and the other minimizes
- ▶ Adversarial, pure competition

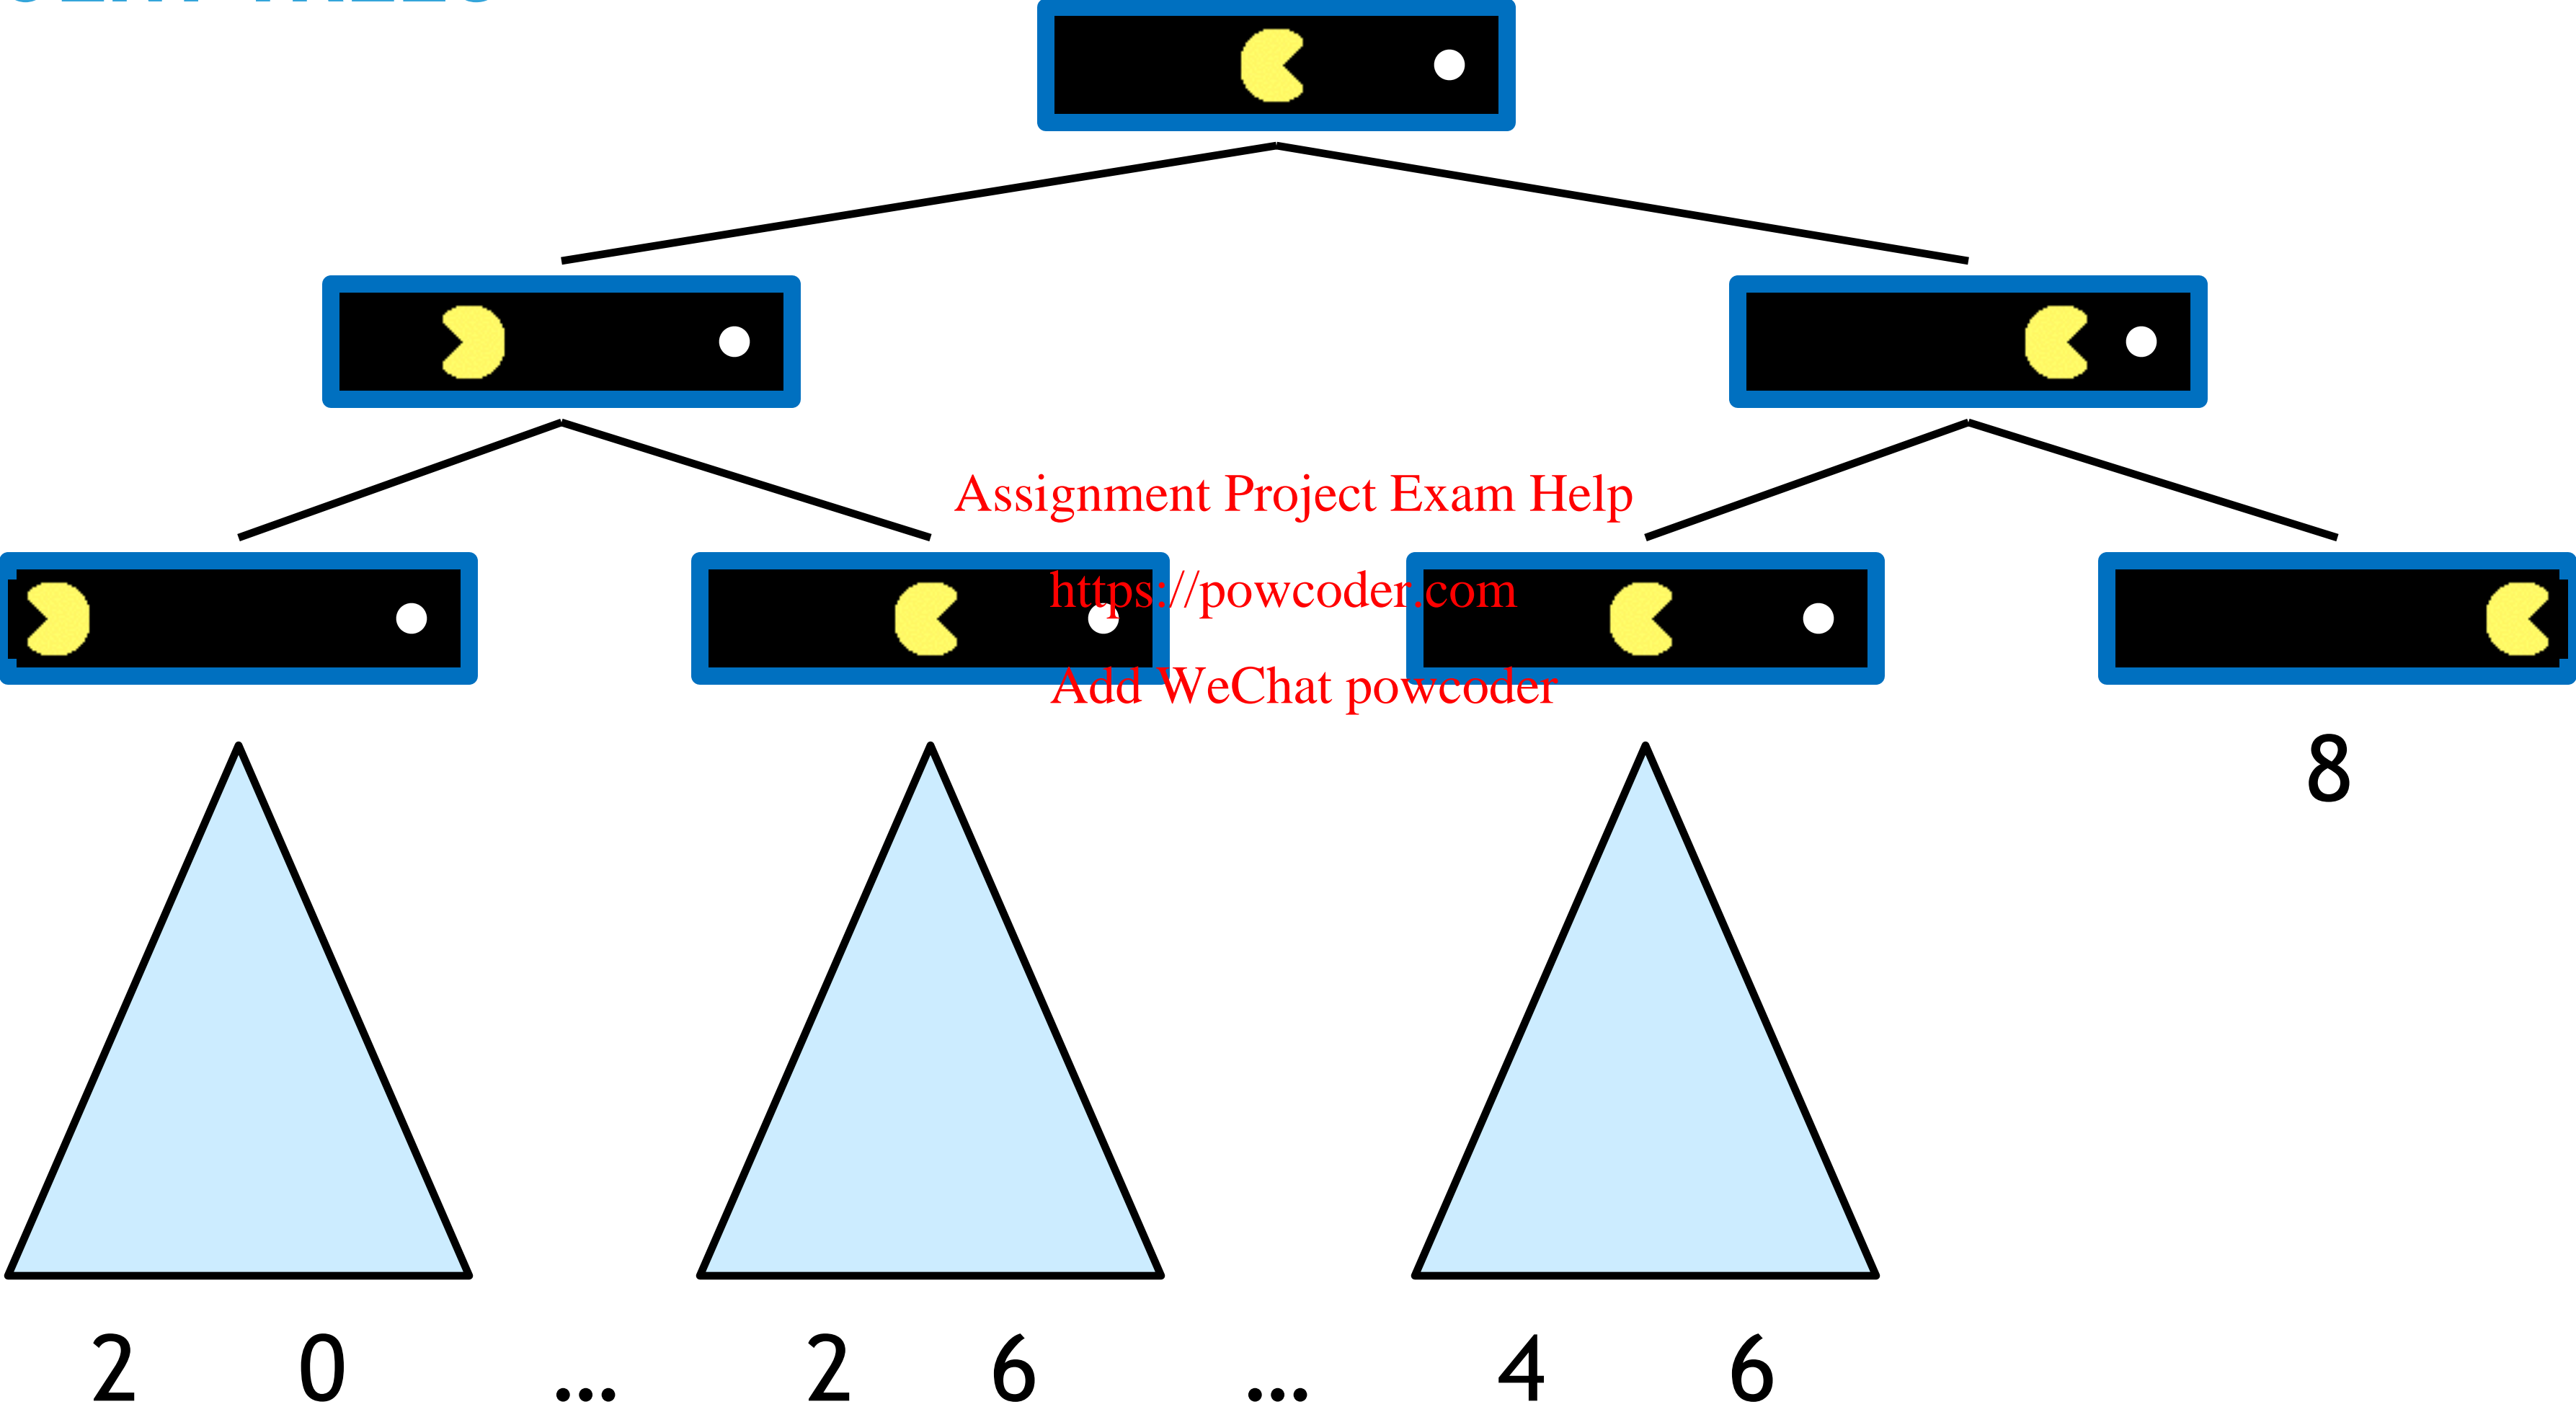

▶ General Games

- ▶ Agents have independent *utilities* (values on outcomes)
- ▶ Cooperation, indifference, competition, and more are all possible
- ▶ More later on non-zero-sum games

ADVERSARIAL SEARCH

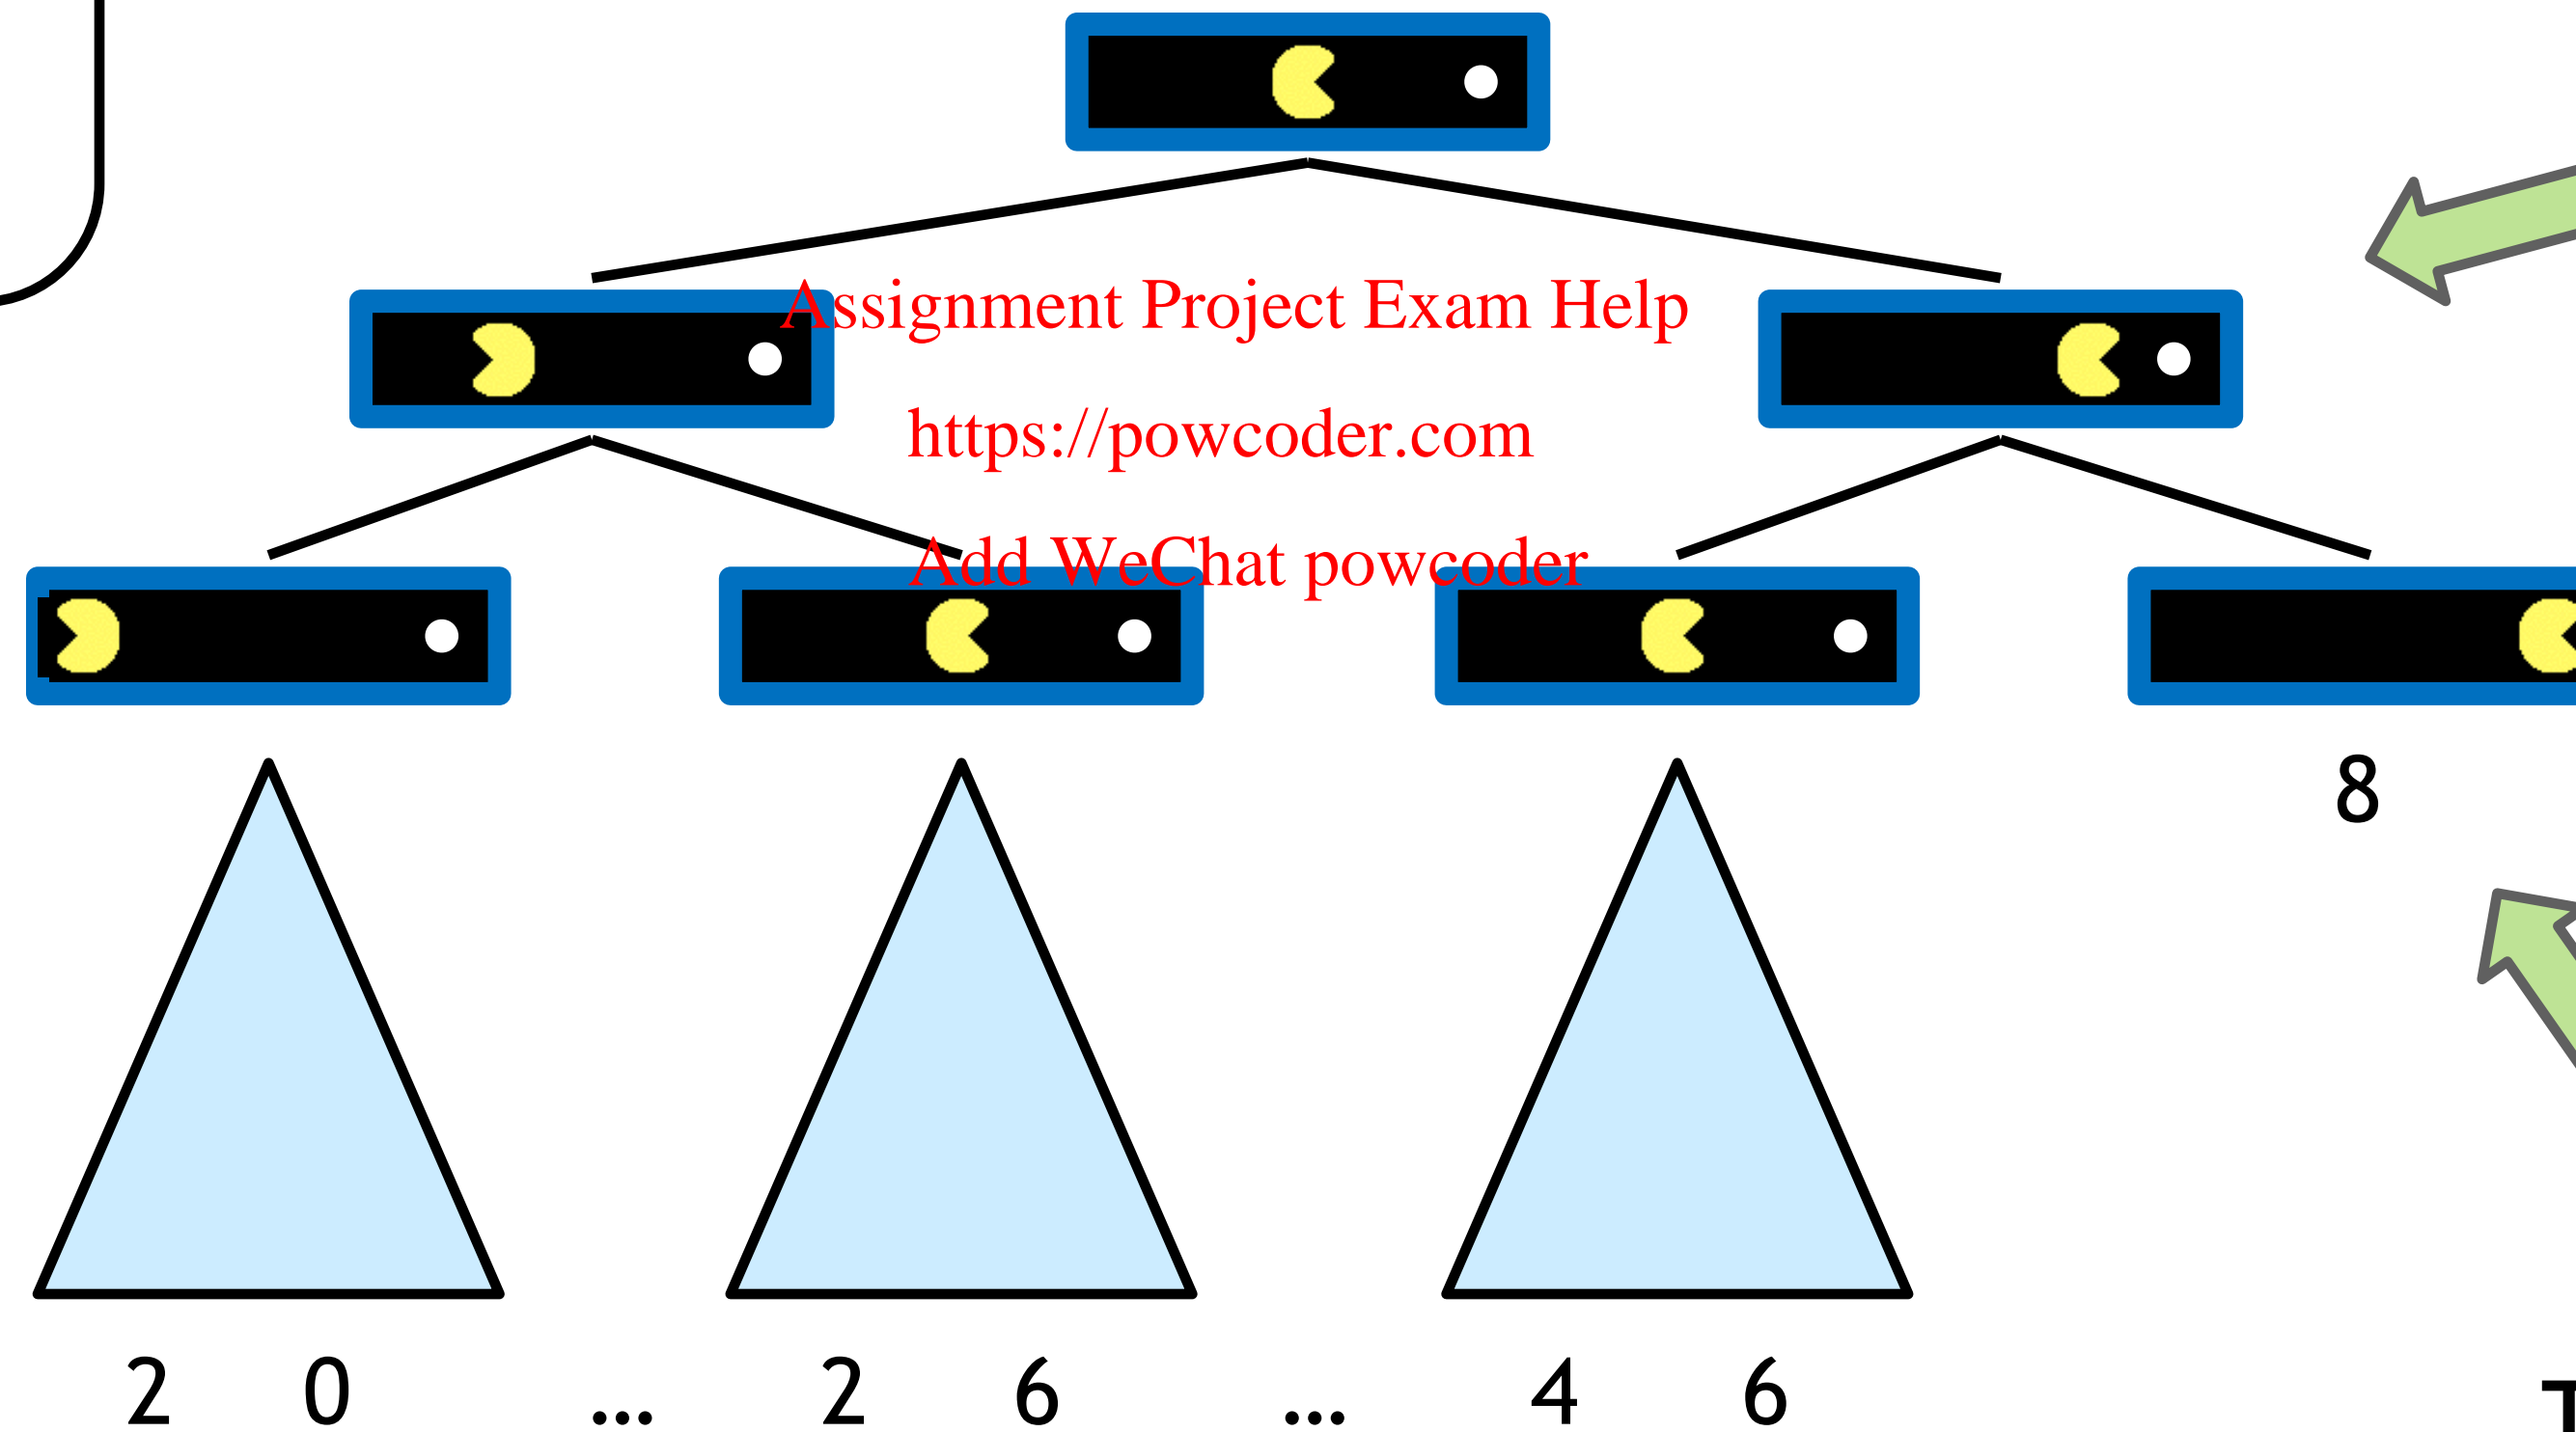

SINGLE-AGENT TREES

VALUE OF A STATE

Value of a state:
The best achievable
outcome (utility) from
that state

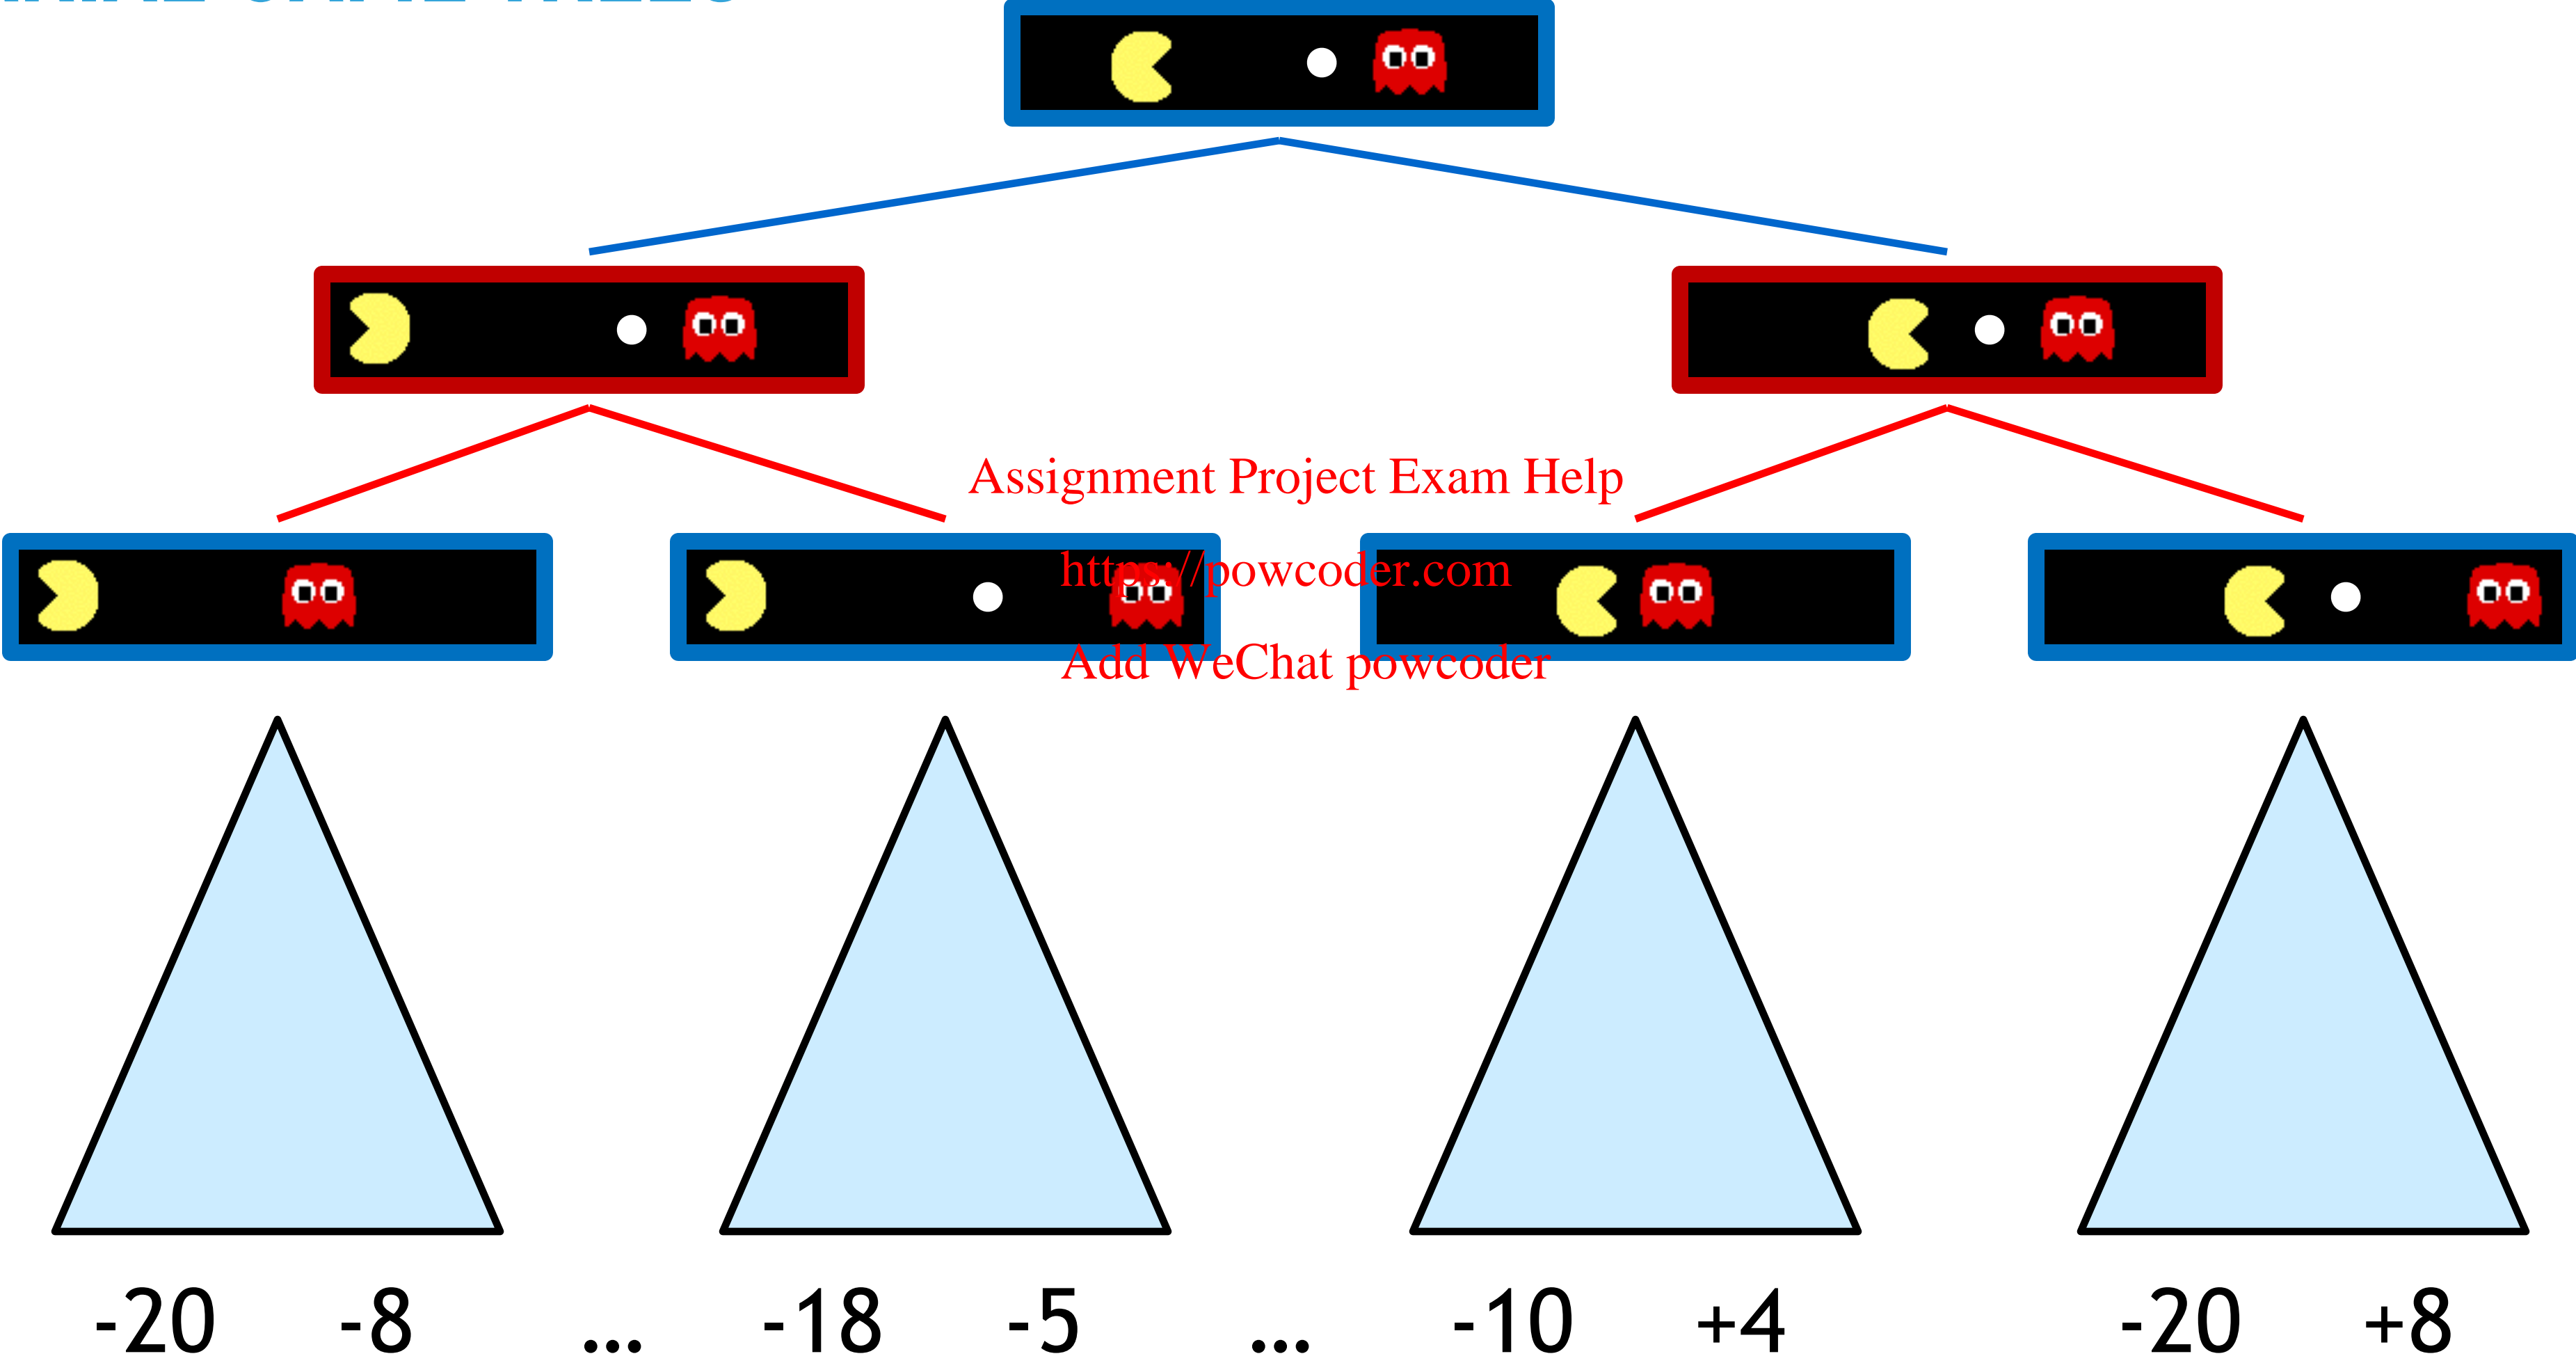

Non-Terminal States:

$$V(s) = \max_{s' \in \text{children}(s)} V(s')$$

Terminal States:

$$V(s) = \text{known}$$

ADVERSARIAL GAME TREES

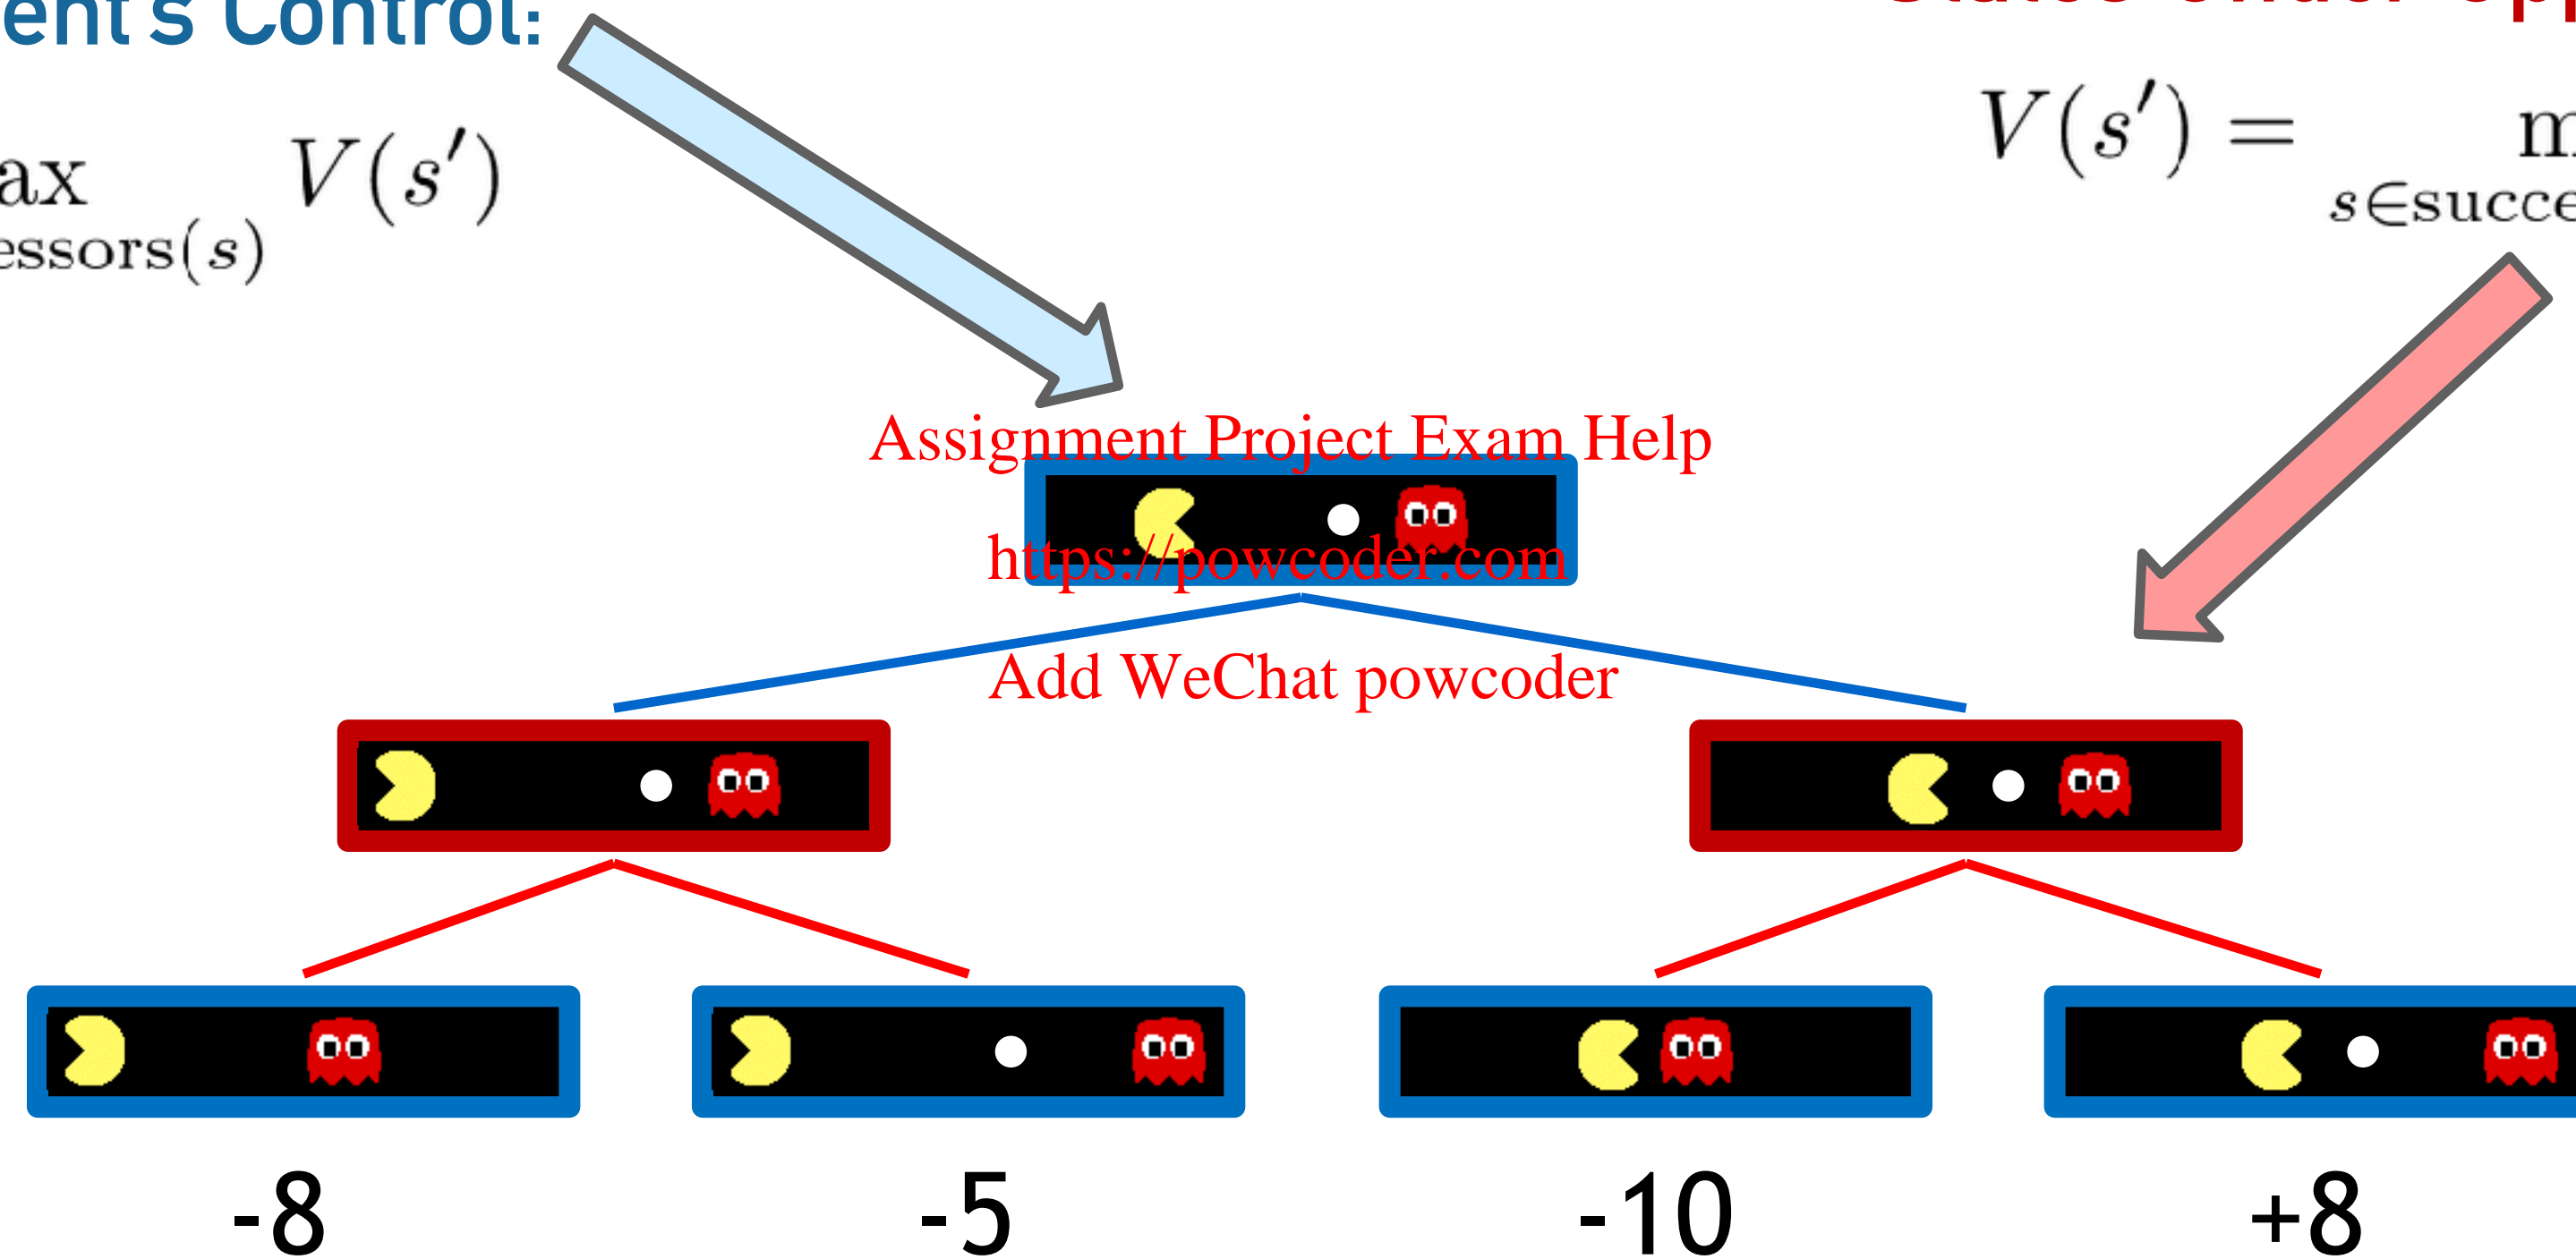

MINIMAX VALUES

States Under Agent's Control:

$$V(s) = \max_{s' \in \text{successors}(s)} V(s')$$

States Under Opponent's Control:

$$V(s') = \min_{s \in \text{successors}(s')} V(s)$$

Terminal States:

$$V(s) = \text{known}$$

TIC-TAC-TOE GAME TREE

MIN (O)

Utility

ADVERSARIAL SEARCH (MINIMAX)

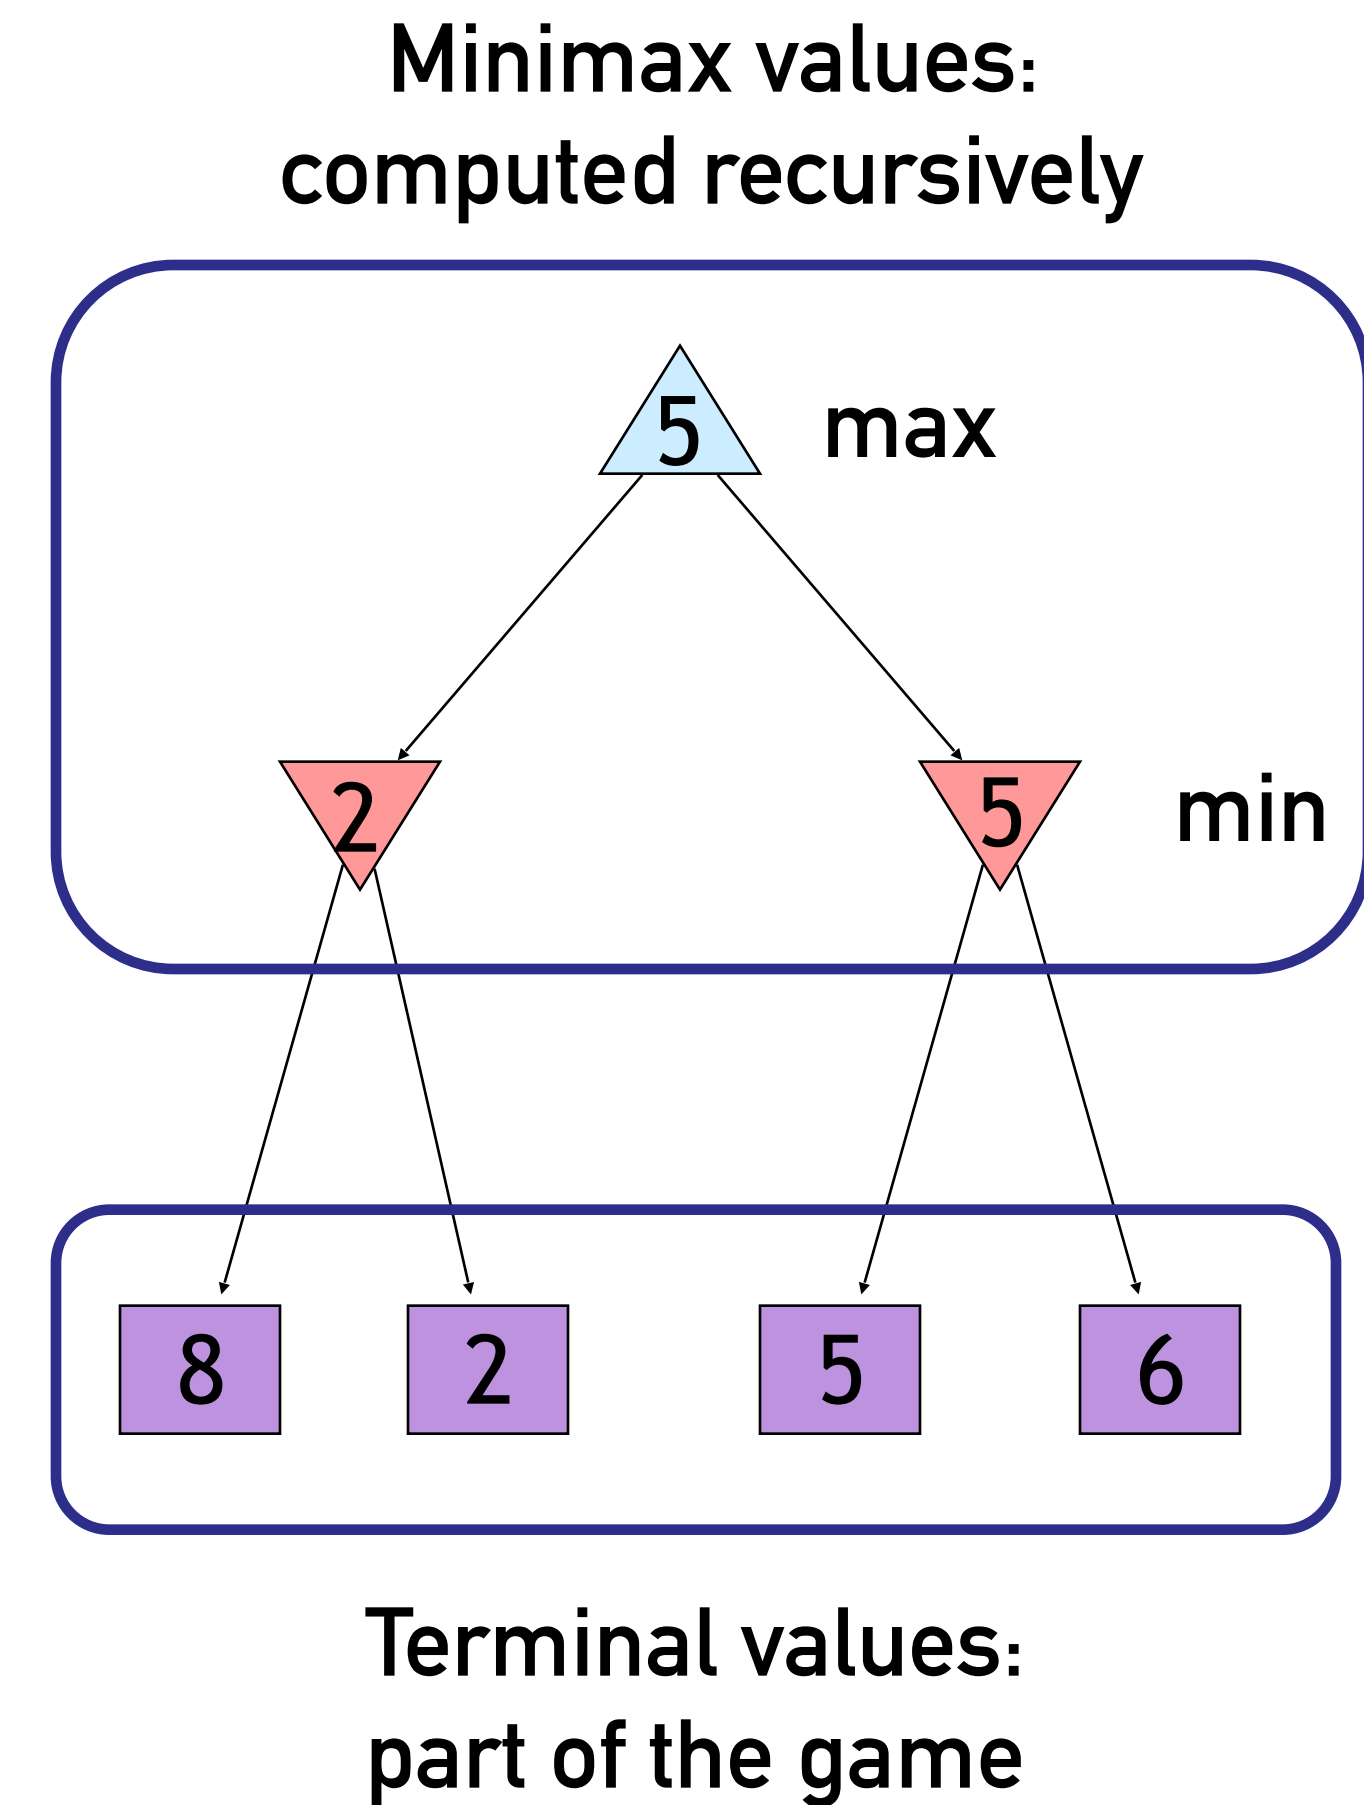

- ▶ Deterministic, zero-sum games:

- ▶ Tic-tac-toe, chess, checkers
- ▶ One player maximizes result
- ▶ The other minimizes result

- ▶ Minimax search:

- ▶ A state-space search tree
- ▶ Players alternate turns
- ▶ Compute each node's **minimax value**: the best achievable utility against a rational (optimal) adversary

MINIMAX IMPLEMENTATION

```
def max-value(state):  
    initialize v =  $-\infty$   
    for each successor of state:  
        v = max(v, min-value(successor))  
    return v
```

$$V(s) = \max_{s' \in \text{successors}(s)} V(s')$$

Assignment Project Exam Help
<https://powcoder.com>
Add WeChat powcoder

```
def min-value(state):  
    initialize v =  $+\infty$   
    for each successor of state:  
        v = min(v, max-value(successor))  
    return v
```

$$V(s') = \min_{s \in \text{successors}(s')} V(s)$$

MINIMAX IMPLEMENTATION (DISPATCH)

```
def value(state):  
    if the state is a terminal state: return the  
        state's utility  
    if the next agent is MAX: return max-value(state)  
    if the next agent is MIN: return min-value(state)
```

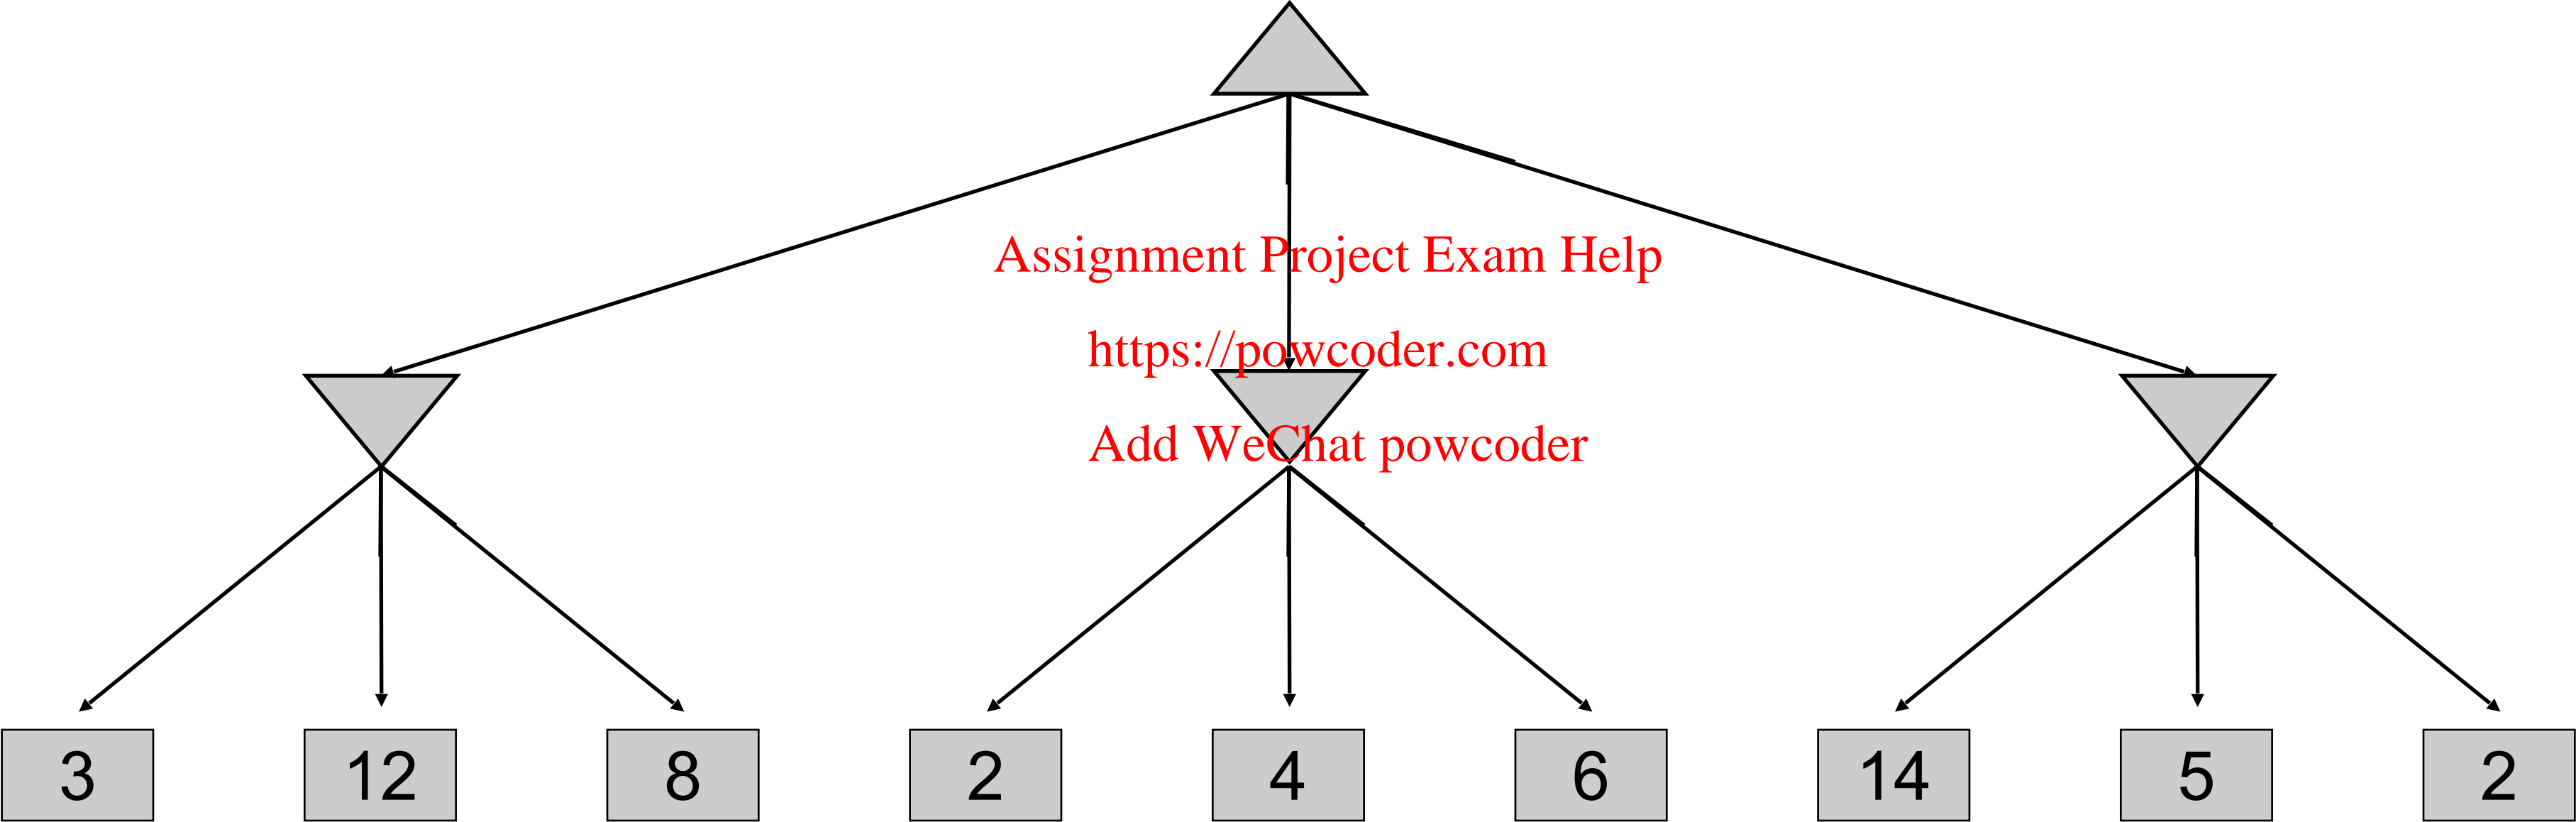

```
def max-value(state):  
    initialize v =  $-\infty$   
    for each successor of state:  
        v = max(v, value(successor))  
    return v
```

```
def min-value(state):  
    initialize v =  $+\infty$   
    for each successor of state:  
        v = min(v, value(successor))  
    return v
```

MINIMAX EXAMPLE

MINIMAX PROPERTIES

Optimal against a perfect player. Otherwise?

MINIMAX EFFICIENCY

- ▶ Efficient of minimax search
 - ▶ Just like (exhaustive) DFS
 - ▶ Time: $O(b^m)$
 - ▶ Space: $O(bm)$
- ▶ Example: For chess, $b \approx 35$, $m \approx 100$
 - ▶ Exact solution is completely infeasible
 - ▶ But, do we need to explore the whole tree?

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

GAME TREE SIZES

- ▶ Tic-tac-toe: 10^5
- ▶ Checkers: 10^{31}
- ▶ Chess: 10^{123}
- ▶ Backgammon: 10^{144}
- ▶ Go: 10^{360}

Assume that a computer can evaluate 1 million board configurations per second.

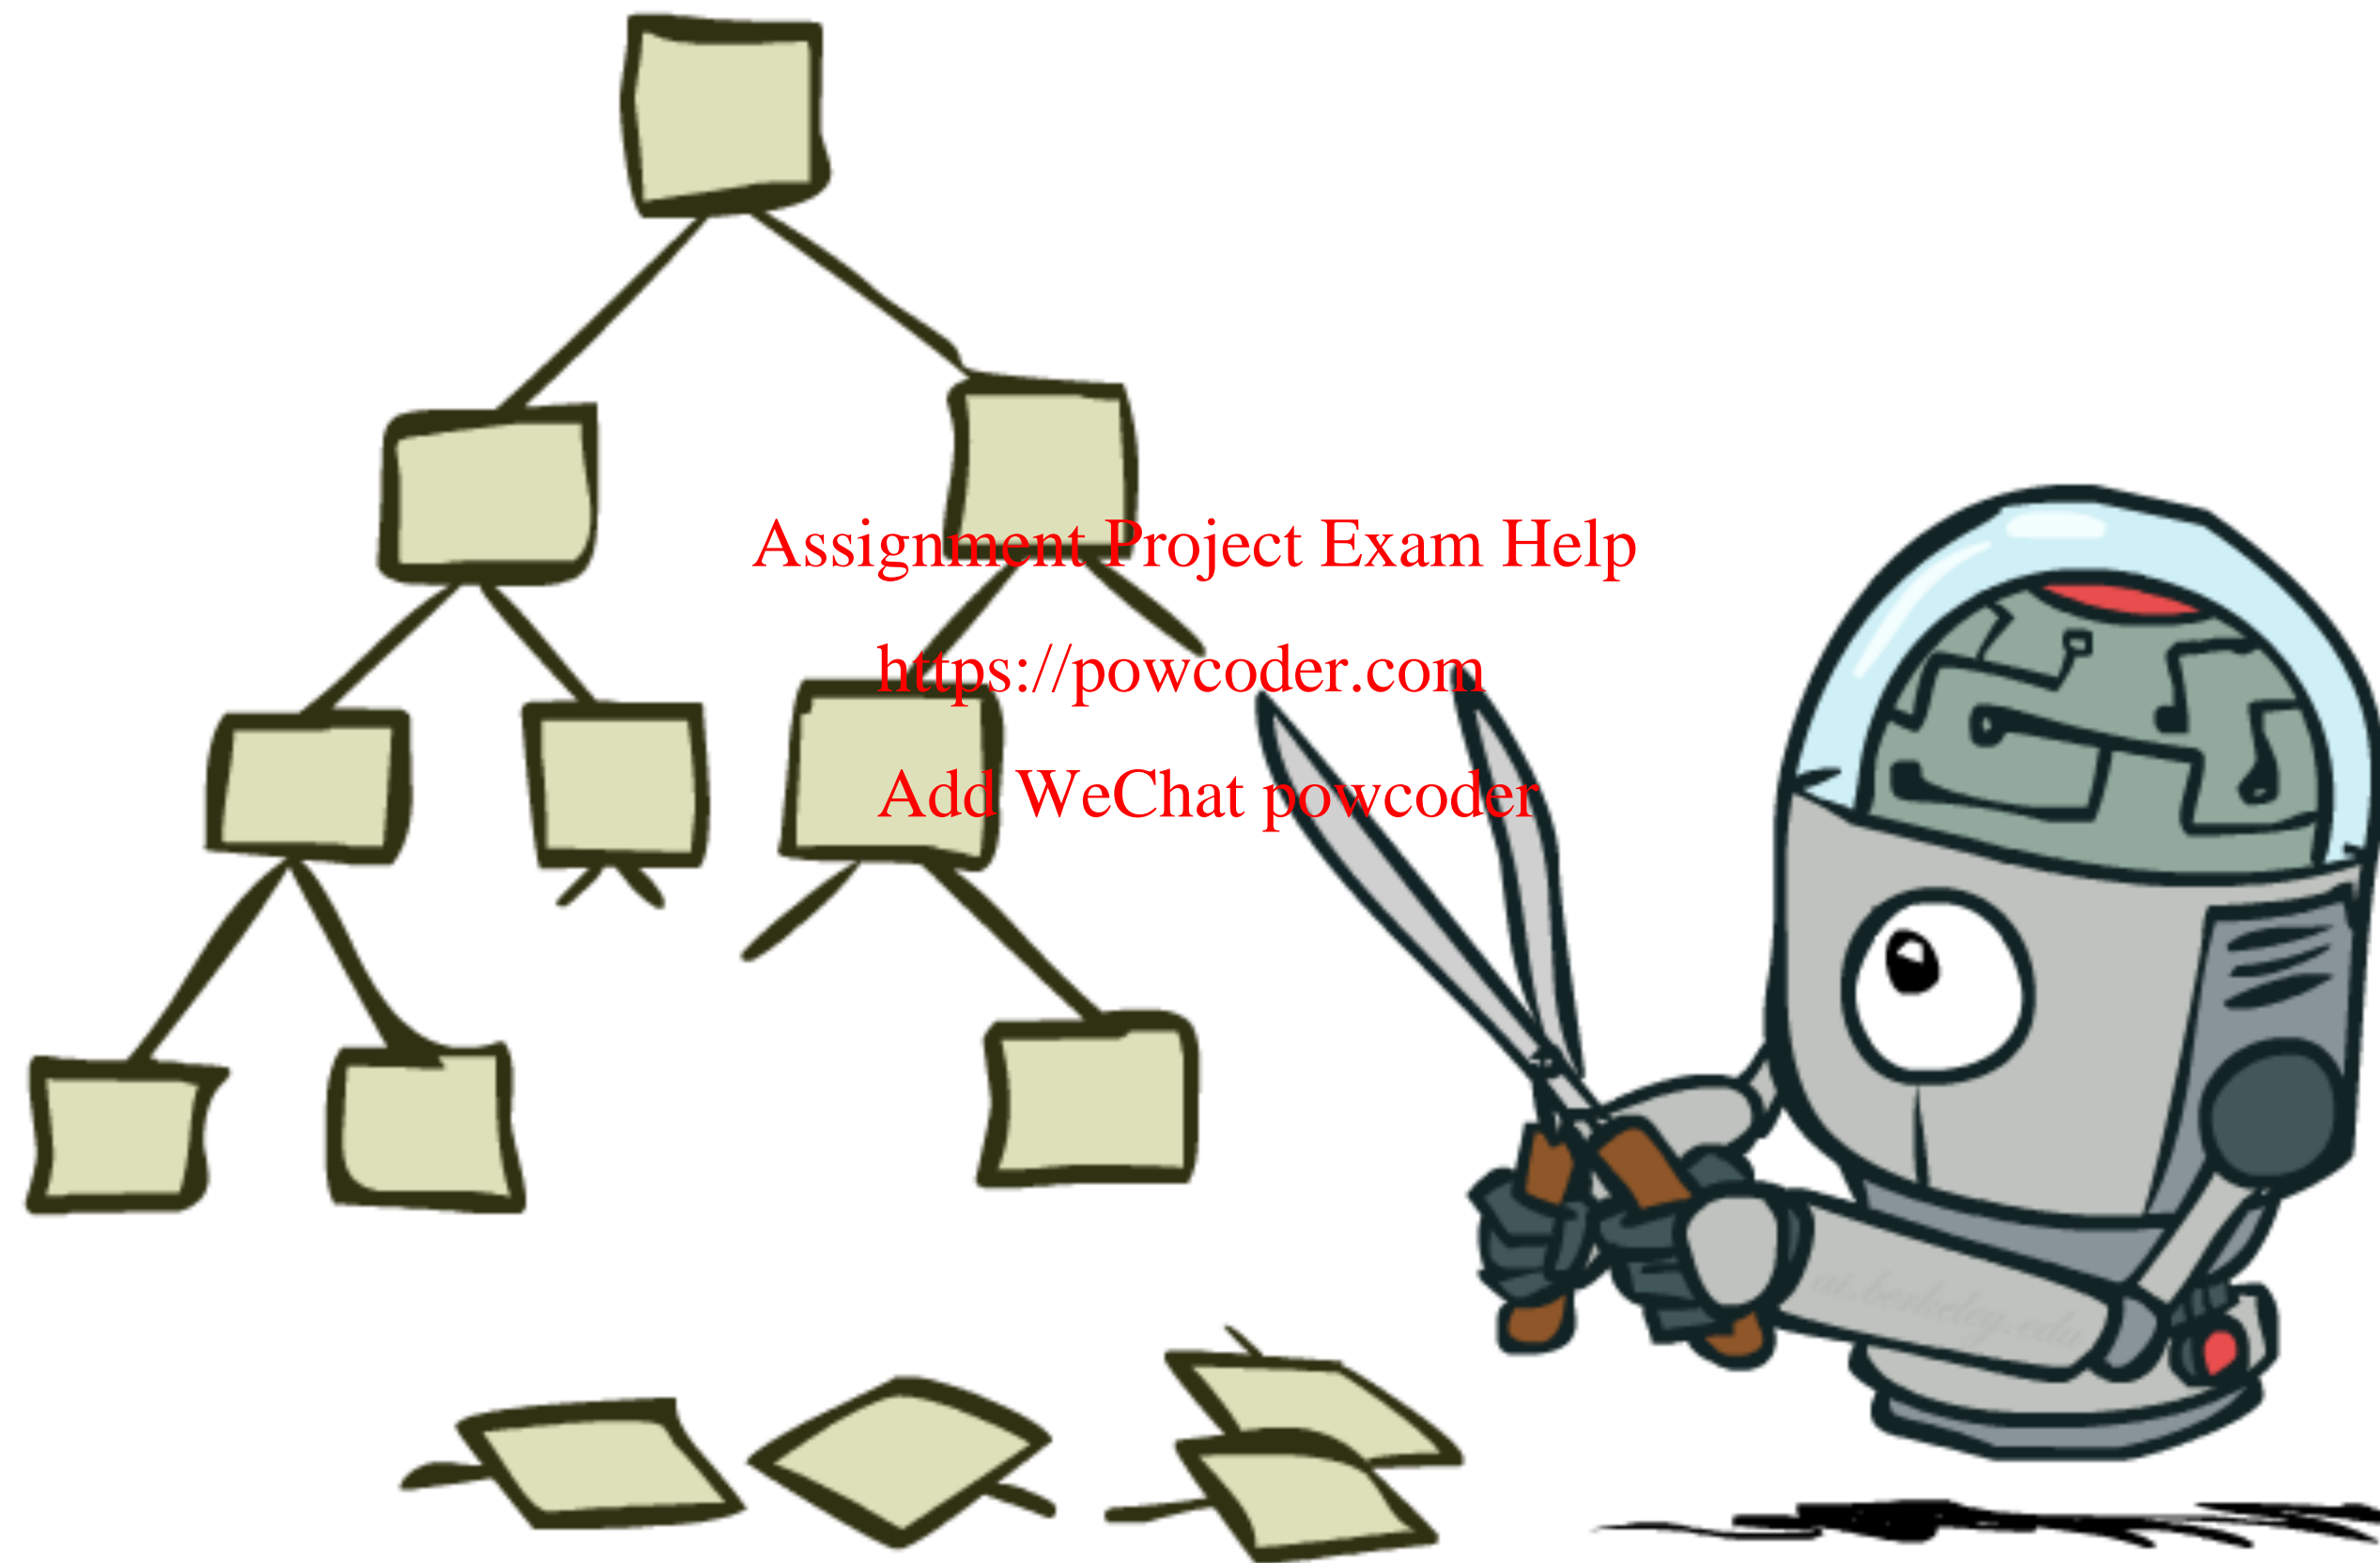

Assignment Project Exam Help

<https://powcoder.com>

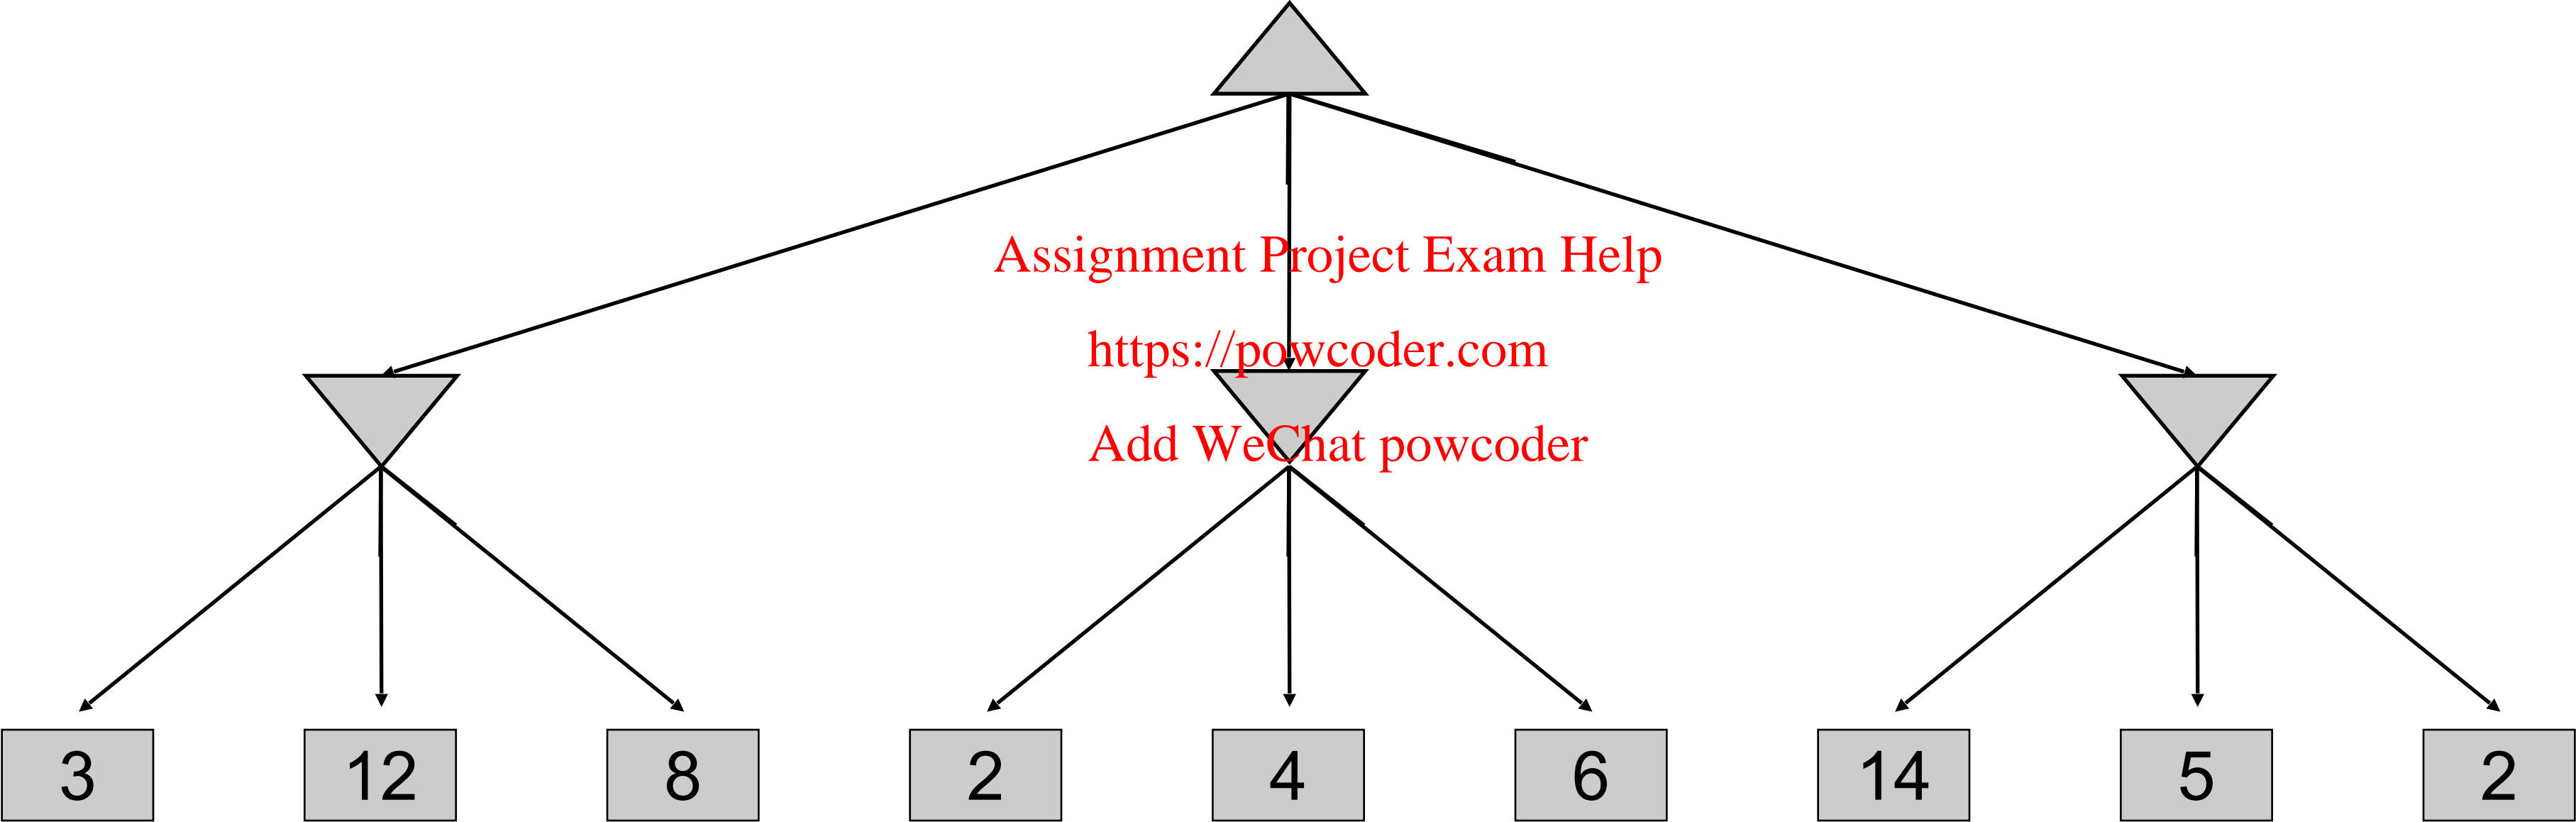

Then it would take **0.1 seconds to search** the entire tic-tac-toe game tree but it would still take **10^{18} years** to search the full checkers tree.

GAME TREE PRUNING

MINIMAX EXAMPLE

MINIMAX PRUNING

ALPHA-BETA PRUNING

- ▶ General configuration (MIN version)
 - ▶ When computing the MIN-VALUE at some node n
 - ▶ We loop over n 's children
 - ▶ n 's estimate of the children's min is dropping
 - ▶ Who cares about n 's value? MAX
 - ▶ Let a be the best value that MAX can get at any choice point along the current path from the root
 - ▶ If n becomes worse than a , MAX will avoid it, so we can stop considering n 's other children (it's already bad enough that it won't be played)
- ▶ MAX version is symmetric

```
def max-value(state,  $\alpha$ ,  $\beta$ ):  
    initialize  $v = -\infty$   
    for each successor of state:  
         $v = \max(v, \text{value}(\text{successor}, \alpha, \beta))$   
        if  $v \geq \beta$  return  $v$   
         $\alpha = \max(\alpha, v)$   
    return  $v$ 
```

```
def min-value(state,  $\alpha$ ,  $\beta$ ):  
    initialize  $v = +\infty$   
    for each successor of state:  
         $v = \min(v, \text{value}(\text{successor}, \alpha, \beta))$   
        if  $v \leq \alpha$  return  $v$   
         $\beta = \min(\beta, v)$   
    return  $v$ 
```

ALPHA-BETA PRUNING PROPERTIES

- ▶ This pruning has **no effect** on minimax value computed for the root
- ▶ Values of intermediate nodes might be wrong
 - ▶ Important: children of the root may have the wrong value
 - ▶ So the most naïve version won't let you do action selection
- ▶ Good child ordering improves effectiveness of pruning
- ▶ With "perfect ordering":
 - ▶ Time complexity drops to $O(b^{m/2})$
 - ▶ Doubles solvable depth
 - ▶ Full search of, e.g. chess, is still hopeless...
- ▶ This is a simple example of **metareasoning** (computing about what to compute)

RESOURCE LIMITS

RESOURCE LIMITS

- ▶ **Problem:** In realistic games, cannot search to leaves
- ▶ **Solution:** Depth-limited search
 - ▶ Instead, search only to a limited depth in the tree
 - ▶ Replace terminal utilities with an evaluation function for non-terminal positions
- ▶ Example:
 - ▶ Suppose we have 100 seconds, can explore 10K nodes / sec
 - ▶ So can check 1M nodes per move
 - ▶ α - β reaches about depth 8 - decent chess program
- ▶ Guarantee of optimal play is gone
- ▶ More plies makes a BIG difference
- ▶ Use iterative deepening for an anytime algorithm

Add WeChat powcoder

DEPTH MATTERS

- ▶ Evaluation functions are always imperfect
- ▶ The deeper in the tree the evaluation function is buried, the less the quality of the evaluation function matters
- ▶ An important example of the tradeoff between complexity of features and complexity of computation

EVALUATION FUNCTIONS

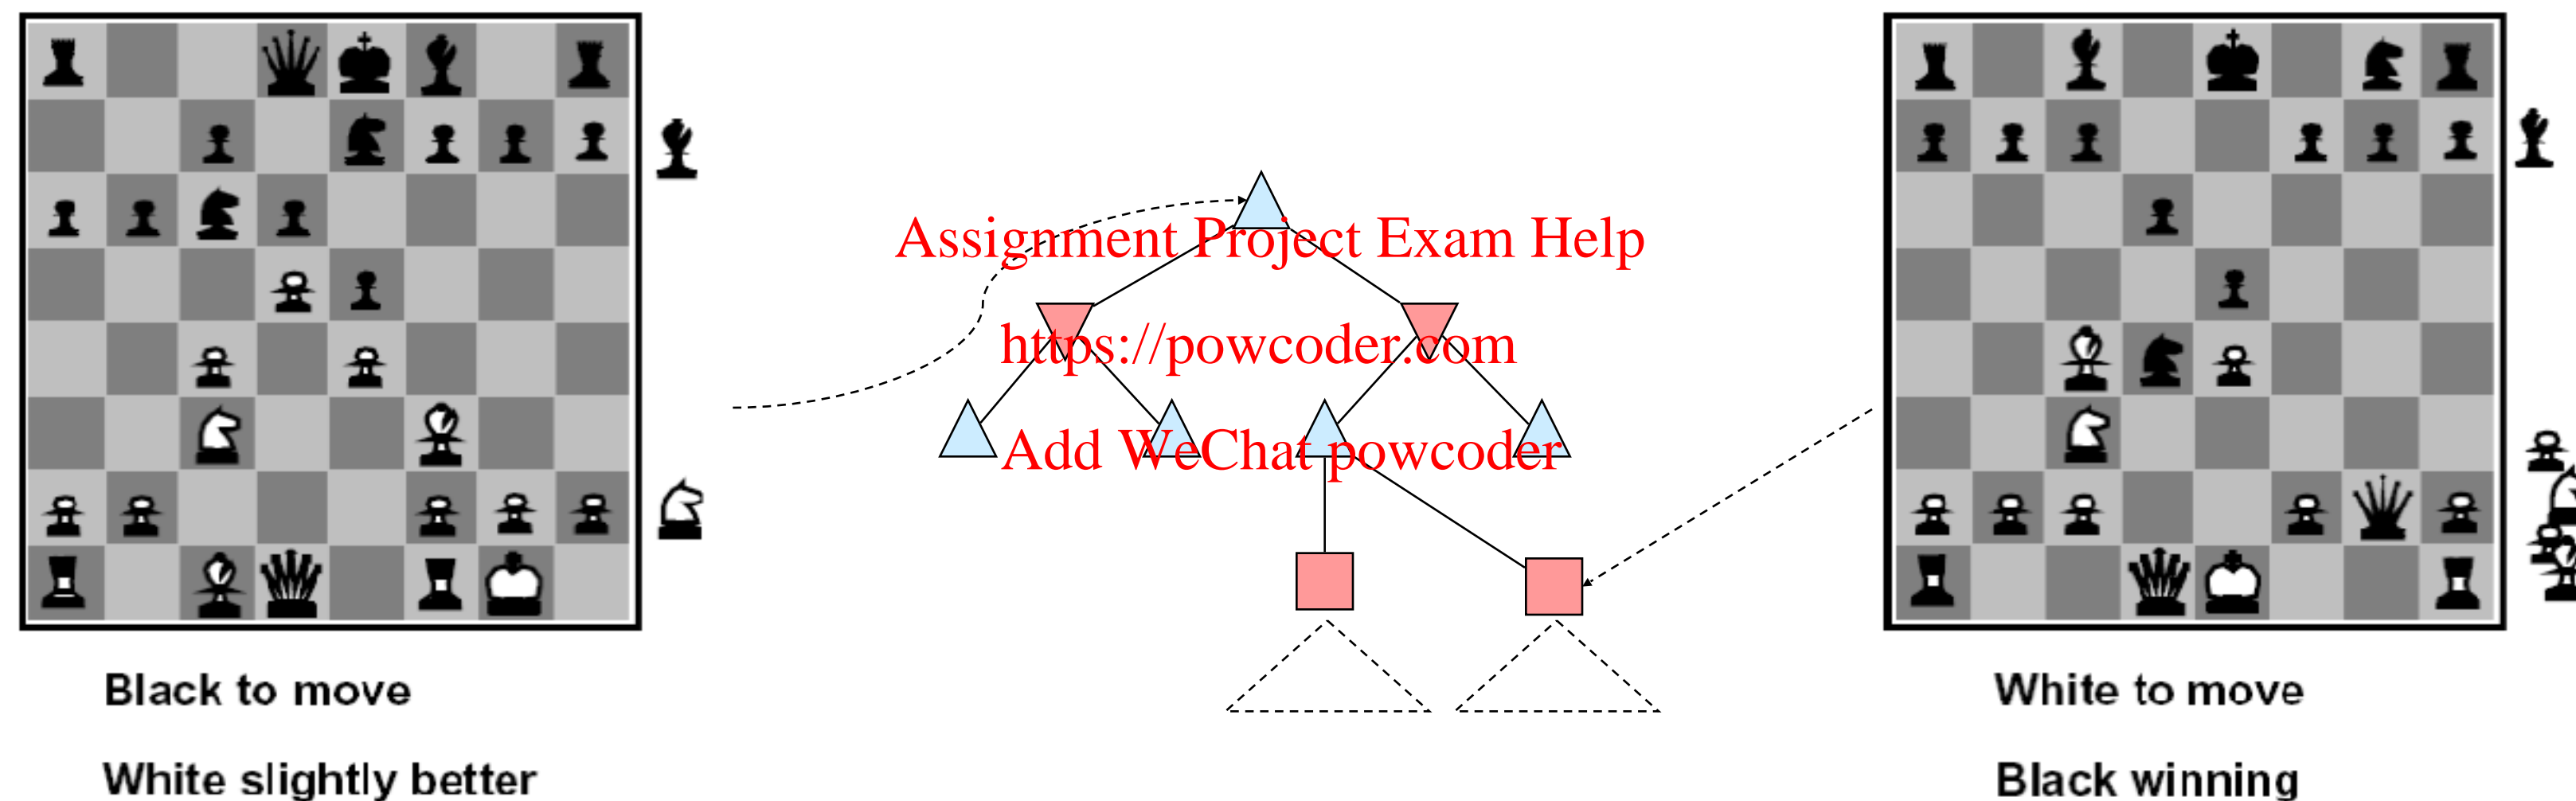

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

EVALUATION FUNCTIONS

- ▶ Evaluation functions score non-terminals in depth-limited search

- ▶ Ideal function: returns the actual minimax value of the position
- ▶ In practice: typically weighted linear sum of features:

$$Eval(s) = w_1 f_1(s) + w_2 f_2(s) + \dots + w_n f_n(s)$$

e.g. $f_1(s) = (\text{num white queens} - \text{num black queens})$, etc.
